Automate your workflow from idea to production

GitHub Actions makes it easy to automate all your software workflows, now with world-class CI/CD. Build, test, and deploy your code right from GitHub. Make code reviews, branch management, and issue triaging work the way you want.

GitHub Actions

- GitHub Actions help you automate tasks within your software development life cycle.
- GitHub Actions are event-driven, meaning that you can run a series of commands after a specified event has occurred.
- For example, every time someone creates a pull request for a repository, you can automatically run a command that executes a software testing script.

The components of GitHub Actions

- Workflows
- Events
- Jobs
- Steps
- Actions
- Runners

Workflow

- The workflow is an automated procedure that you add to your repository.
- Workflows are made up of one or more jobs and can be scheduled or triggered by an event.
- The workflow can be used to build, test, package, release, or deploy a project on GitHub.

Events

- An event is a specific activity that triggers a workflow.
- Examples
 - Activity can originate from GitHub when someone pushes a commit to a repository or when an issue or pull request is created.
 - You can also use the repository dispatch webhook to trigger a workflow when an external event occurs.

Events That Trigger Workflows

- Scheduled events
 - schedule
- Manual events
 - workflow_dispatch
 - repository_dispatch
- Webhook events
 - check run
 - check_suite
 - create
 - delete
 - deployment
 - deployment_status
 - fork
 - gollum

- Webhook events (contd.)
 - issue_comment
 - issues
 - label
 - milestone
 - page build
 - project
 - project_card
 - project_column
 - public
 - pull request
 - pull_request_review
 - pull_request_review_comment
 - pull_request_target
 - push
 - registry_package
 - release
 - status
 - watch
 - workflow_run

Jobs

- A job is a set of steps that execute on the same runner.
- By default, a workflow with multiple jobs will run those jobs in parallel.
- You can also configure a workflow to run jobs sequentially.
- Example
 - A workflow can have two sequential jobs that build and test code, where the
 test job is dependent on the status of the build job. If the build job fails, the
 test job will not run.

Steps

- A step is an individual task that can run commands in a job.
- A step can be either an action or a shell command.
- Each step in a job executes on the same runner, allowing the actions in that job to share data with each other.

Actions

- Actions are standalone commands that are combined into steps to create a job.
- Actions are the smallest portable building block of a workflow.
- You can create your own actions, or use actions created by the GitHub community.
- To use an action in a workflow, you must include it as a step.

Runners

- A runner is a server that has the GitHub Actions runner application installed.
- You can use a runner hosted by GitHub, or you can host your own.
- A runner listens for available jobs, runs one job at a time, and reports the progress, logs, and results back to GitHub.
- GitHub-hosted runners are based on Ubuntu Linux, Microsoft Windows, and macOS, and each job in a workflow runs in a fresh virtual environment.

Writing GitHub Actions

- GitHub Actions uses **YAML** syntax to define the events, jobs, and steps.
- GitHub Actions YAML files are stored in your code repository, in a directory called .github/workflows.

Sample Workflow

```
name: learn-github-actions
on: [push]
jobs:
    check-bats-version:
        runs-on: ubuntu-latest
        steps:
        - uses: actions/checkout@v2
        - uses: actions/setup-node@v1
        - run: npm install -g bats
        - run: bats -v
```

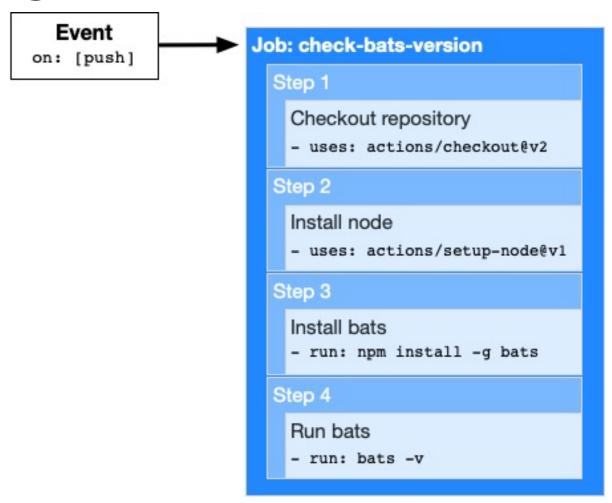

Understanding The Workflow File (1)

name: learn-github-actions	Optional - The name of the workflow as it will appear in the Actions tab of the GitHub repository.
on: [push]	Specify the event that automatically triggers the workflow file. This example uses the push event, so that the jobs run every time someone pushes a change to the repository. You can set up the workflow to only run on certain branches, paths, or tags. For syntax examples including or excluding branches, paths, or tags, see "Workflow syntax for GitHub Actions."
jobs:	Groups together all the jobs that run in the learn-github-actions workflow file.
check-bats-version:	Defines the name of the check-bats-version job stored within the jobs section.
runs-on: ubuntu-latest	Configures the job to run on an Ubuntu Linux runner. This means that the job will execute on a fresh virtual machine hosted by GitHub. For syntax examples using other runners, see "Workflow syntax for GitHub Actions."

Understanding The Workflow File (contd)

steps:	Groups together all the steps that run in the check-bats-version job. Each item nested under this section is a separate action or she command.
<pre>- uses: actions/checkout@v2</pre>	The uses keyword tells the job to retrieve v2 of the community action named actions/checkout@v2. This is an action that checks out your repository and downloads it to the runner, allowing you to run actions against your code (such as testing tools). You must use the checkout action any time your workflow will run against the repository's code or you are using an action defined in the repository.
<pre>- uses: actions/setup-node@v1</pre>	This action installs the node software package on the runner, giving you access to the npm command.
– run: npm install –g bats	The run keyword tells the job to execute a command on the runner of the later of th
- run: bats -v	Finally, you'll run the bats command with a parameter that output the software version.

Visualizing The Workflow File

Viewing The Job's Activity

Once your job has started running, you can see a visualization graph of the run's progress and view each step's activity on GitHub.

- 1 On GitHub, navigate to the main page of the repository.
- 2 Under your repository name, click Actions.

3 In the left sidebar, click the workflow you want to see.

4 Under "Workflow runs", click the name of the run you want to see.

Viewing The Job's Activity (contd.)

5 Under Jobs or in the visualization graph, click the job you want to see. Update main.yml learn-github-actions #10 Re-run jobs - · · · Summary Triggered by push 5d ago Status Total duration Artifacts Octocat pushed -o- c5ce0db main Success 23s check-bats-version main.yml on: push check-bats-version 6 View the results of each step. Summary check-bats-version **1633** succeeded 8 minutes ago in 9s Jobs Set up job check-bats-version Run actions/checkout@v2 Run actions/setup-node@v1 Run npm install -g bats Run bats -v 0s ► Run bats -v Bats 1.2.1 Post Run actions/checkout@v2 Complete job

Managing Workflow Runs

- You can view the status and results of each step in your workflow, cancel a pending workflow, review deployments, view billable job execution minutes, debug and re-run a failed workflow, search and download logs, and download artifacts.
- https://docs.github.com/en/actions/managing-workflow-runs

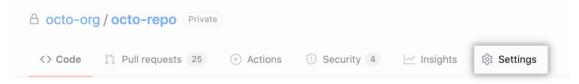

Encrypted Secrets

- Encrypted secrets allow you to store sensitive information in your organization, repository, or repository environments.
- Secrets are encrypted environment variables that you create in an organization, repository, or repository environment.
- The secrets that you create are available to use in GitHub Actions workflows.
- GitHub uses a libsodium sealed box to help ensure that secrets are encrypted before they reach GitHub and remain encrypted until you use them in a workflow.
- https://docs.github.com/en/actions/reference/encrypted-secrets

Creating Encrypted Secrets For A Repository

To create secrets for a user account repository, you must be the repository owner. To create secrets for an organization repository, you must have admin access.

- 1 On GitHub, navigate to the main page of the repository.
- 2 Under your repository name, click & Settings.

- 3 In the left sidebar, click Secrets.
- 4 Click New repository secret.
- 5 Type a name for your secret in the Name input box.
- 6 Enter the value for your secret.
- 7 Click Add secret.

Using Encrypted Secrets In A Workflow

- To provide an action with a secret as an input or environment variable, you can use the secrets context to access secrets you've created in your repository.
- Avoid passing secrets between processes from the command line, whenever possible.
- Command-line processes may be visible to other users (using the ps command) or captured by security audit events.
- To help protect secrets, consider using environment variables, STDIN, or other mechanisms supported by the target process.
- If you must pass secrets within a command line, then enclose them within the proper quoting rules.
- Secrets often contain special characters that may unintentionally affect your shell.
- To escape these special characters, use quoting with your environment variables.
- Secrets are limited to 64 KB in size.

```
steps:
    - name: Hello world action
    with: # Set the secret as an input
        super_secret: ${{ secrets.SuperSecret }}
    env: # Or as an environment variable
        super_secret: ${{ secrets.SuperSecret }}
```

Example using Bash

```
steps:
    - shell: bash
    env:
        SUPER_SECRET: ${{ secrets.SuperSecret }}
    run: |
        example-command "$SUPER_SECRET"
```

GitHub Action for AMI Pull Request

```
github > workflows > m pull-requests.yml > { } jobs > { } validate > [ ] steps
      You, seconds ago I 1 author (You)
     name: Packer Validate on Pull Requests
 4 # Controls when the action will run.
     # Triggers the workflow on push or pull request events but only for the main branch
         branches: [ master ]
      # This workflow contains a single job called "build"
         # The type of runner that the job will run on
         runs-on: ubuntu-latest
         *# Steps represent a sequence of tasks that will be executed as part of the job
         # Checks-out your repository under $GITHUB_WORKSPACE, so your job can access it
         - name: Checkout Repository
           uses: actions/checkout@v2
          - name: Validate Packer Template
            uses: hashicorp/packer-github-actions@master
             command: validate
             arguments: -syntax-only # only validate syntax
             target: ami.json
             PACKER_LOG: 1 # enable debug log for packer
